Lab: Objects & Composition

Problems for in-class lab for the "JavaScript Advanced" course @ SoftUni. Submit your solutions in the SoftUni judge system at https://judge.softuni.bg/Contests/2758/Objects-and-Composition-Lab.

1. City Record

You will receive a city's **name** (string), **population** (number), and **treasury** (number) as arguments, which you will need to set as **properties** of an **object** and **return** it.

Examples

Input	Output

'Tortuga',
7000,
15000
	{
	  name: 'Tortuga',
	  population: 7000,
	  treasury: 15000
	}

'Santo Domingo',
12000,
23500
	{
	  name: 'Santo Domingo',
	  population: 12000,
	  treasury: 23500
	}

2. Town Population

You have been tasked to create a registry for different **towns** and their **population**.

Input

The **input** comes as array of strings. Each element will contain data for a town and its population in the following format: **"{townName} <-> {townPopulation}"**

If you receive the same town twice, **you should add** the **given population** to the **current one**.

Output

As **output**, you must print all the towns and their population.

Examples

Input	Output
['Sofia <-> 1200000', 'Montana <-> 20000', 'New York <-> 10000000', 'Washington <-> 2345000', 'Las Vegas <-> 1000000']	Sofia : 1200000 Montana : 20000 New York : 10000000 Washington : 2345000 Las Vegas : 1000000
['Istanbul <-> 100000', 'Honk Kong <-> 2100004', 'Jerusalem <-> 2352344', 'Mexico City <-> 23401925', 'Istanbul <-> 1000']	Istanbul : 101000 Honk Kong : 2100004 Jerusalem : 2352344 Mexico City : 23401925

3. City Taxes

This task is an extension of Problem 1, you may use your solution from that task as a base.

You will receive a city's **name** (string), **population** (number), and **treasury** (number) as arguments, which you will need to set as **properties** of an **object** and **return** it. In addition to the input parameters, the object must have a property **`taxRate`** with an initial value of **10**, and three **methods** for managing the city:

- **`collectTaxes()`** - Increase **treasury** by **`population * taxRate`**
- **`applyGrowth(percentage)`** - Increase population by **given percentage**
- **`applyRecession(percentage)`** - Decrease treasury by **given percentage**

Round down the values after each calculation.

Input

Your solution will receive three **valid** parameters. The methods that expect parameters will be tested with valid input.

Output

Return an **object** as described above. The methods of the object modify the object and don't return anything.

Input	Output
`const city = cityTaxes('Tortuga', 7000, 15000); console.log(city);`	`{ name: 'Tortuga', population: 7000, treasury: 15000, taxRate: 10, collectTaxes: [Function: collectTaxes], applyGrowth: [Function: applyGrowth], applyRecession: [Function: applyRecession] }`
Testing with code	
Input	**Output**
`const city = cityTaxes('Tortuga', 7000, 15000); city.collectTaxes(); console.log(city.treasury); city.applyGrowth(5); console.log(city.population);`	`85000` `7350`

4. Object Factory

Create a function that can compose objects by copying functions from a given library of functions. You will receive **two parameters** – a **library** of functions as an associative array (object) and an **array of orders**, represented as objects**.** You must **return** a new array – the fulfilled orders.

The **first parameter** will be an object where each property is a **function**. You will use this **library of functions** to compose new objects.

The **second parameter** is an **array of orders**. Each order is an **object** with the following shape:

```
{
  template: [Object],
  parts: string[]
}
```

A **template** is an object that must be **copied**. The **parts array** contains the names of **required functions** as **strings**.

You must **create and return a new array**, by fulfilling all orders from the **orders array**. To fulfill an order, create a copy of the object's template and then add to it all functions, listed in the **parts array** of the order, by taking them from the **function library** (the first parameter to your solution).

Input

You will receive two parameters:

- **`library`** – an object
- **`orders`** – an array of objects

Output

Your solution must **return an array** of objects.

Example

Input

```
const library = {
  print: function () {
    console.log(`${this.name} is printing a page`);
  },
  scan: function () {
    console.log(`${this.name} is scanning a document`);
  },
  play: function (artist, track) {
    console.log(`${this.name} is playing '${track}' by ${artist}`);
  },
};
const orders = [
  {
    template: { name: 'ACME Printer'},
    parts: ['print']
  },
  {
    template: { name: 'Initech Scanner'},
    parts: ['scan']
  },
  {
    template: { name: 'ComTron Copier'},
    parts: ['scan', 'print']
  },
  {
    template: { name: 'BoomBox Stereo'},
    parts: ['play']
  }
];
```

```
const products = factory(library, orders);
console.log(products);
```

Output

```
[
  {
    name: 'ACME Printer',
    print: [Function: print]
  },
  {
    name: 'Initech Scanner',
    scan: [Function: scan]
  },
  {
    name: 'ComTron Copier',
    scan: [Function: scan],
    print: [Function: print]
  },
  {
    name: 'BoomBox Stereo',
    play: [Function: play]
  }
]
```

5. Assembly Line

Create a function that **returns** a **library of decorator functions**. They can be used to **compose** different functionality in a **car object** that they receive as an argument.

Your solution must **return an object**, containing **three decorator functions**:

`hasClima` – compose air conditioning controls into the passed-in object. This function takes an **object as a parameter** and adds to it the following properties:

- **`temp`** – **number** with default value **21**;
- **`tempSettings`** – **number** with default value **21**;
- **`adjustTemp`** – **function** which takes **no arguments**. If **`temp`** is less than **`tempSettings`**, this function adds 1 to **`temp`**. If **`temp`** is more than **`tempSettings`**, it decreases **`temp`** by 1. If **`temp`** and **`tempSettings`** are equal, the function does nothing.

`hasAudio` – compose audio player functionality into the passed-in object. This function takes an **object as a parameter** and adds to it the following properties:

- **`currentTrack`** – **object** with properties **`name`** (string) and **`artist`** (string). The default value is **`null`**;
- **`nowPlaying`** – **function**, which **prints** on the console the text:
  `` `Now playing '${currentTrack.name}' by ${currentTrack.artist}` ``, where **`name`** and **`artist`** are properties of the **`currentTrack`** object. If **`currentTrack`** is **`null`**, this function does nothing.

`hasParktronic` – compose parking aid functionality into the passed in object. This function takes an **object as a parameter** and adds to it the following properties:

- **`checkDistance`** – **function**, which takes a **single argument `distance`** (number) and **prints** a message on the console, depending on its value:

distance < 0.1 – **"Beep! Beep! Beep!"**
0.1 <= **distance** < 0.25 – **"Beep! Beep!"**
0.25 <= **distance** < 0.5 – **"Beep!"**

In any other case, print an **empty string**.

Input

Your **solution** will receive **no arguments**. All the methods in the returned library must take an **object as an argument**. Any methods that you compose into this object must meet the input requirements listed in the description above.

Output

Your **solution** must **return an object** containing the **three decorators** described above.

Example

Setup

```
const assemblyLine = createAssemblyLine();

const myCar = {
    make: 'Toyota',
    model: 'Avensis'
};
```

Input	Output

`assemblyLine.hasClima(myCar);`
`console.log(myCar.temp);`
`myCar.tempSettings = 18;`
`myCar.adjustTemp();`
`console.log(myCar.temp);`
	`21`
	`20`

Input	Output

`assemblyLine.hasAudio(myCar);`
`myCar.currentTrack = {`
`  name: 'Never Gonna Give You Up',`
`  artist: 'Rick Astley'`
`};`
`myCar.nowPlaying();`
	`Now playing 'Never Gonna Give You Up'`
	`by Rick Astley`

Input	Output

`assemblyLine.hasParktronic(myCar);`
`myCar.checkDistance(0.4);`
`myCar.checkDistance(0.2);`
	`Beep!`
	`Beep! Beep!`

Input	Output

`console.log(myCar);`	`{`
	`  make: 'Toyota',`
	`  model: 'Avensis',`
	`  temp: 20,`
	`  tempSettings: 18,`
	`  adjustTemp: [Function],`
	`  currentTrack: {`
	`  name: 'Never Gonna Give You Up',`
	`  artist: 'Rick Astley'`
	`  },`

	nowPlaying: [Function], checkDistance: [Function] }

6. From JSON to HTML Table

You're tasked with creating an HTML table of students and their scores. You will receive a single string representing an **array of objects**, the **table's headings** should be equal to the **object's keys**, while **each object's values** should be a **new entry** in the table. Any **text values** in an object should be **escaped**, to avoid introducing dangerous code into the HTML.

Input

The **input** comes with a **single string argument** (the array of objects).

Output

The **output** should be printed on the console – for each **entry row** in the input print the **object representing it**.

Note:

Objects' **keys** will always be the **same.** Check more information for the **HTML Entity** here**.**

HTML

You are provided with an HTML file to test your table in the browser.

index.html

```
<!DOCTYPE html>
<html lang="en">
<head>
    <meta charset="UTF-8">
    <title>FromJSONToHTMLTable</title>
    <style>
        table,th{
            border: groove;
            border-collapse: collapse;
        }
        td{
            border: 1px solid black;
        }
        td,th{
            padding: 5px;
        }
    </style>
</head>
<body>
    <div id="wrapper">
    </div>
    <script>
        function fromJSONToHTMLTable(input){
            //Write your code here
        }
        window.onload = function(){
            let container = document.getElementById('wrapper');
            container.innerHTML =
fromJSONToHTMLTable(['[{"Name":"Stamat","Price":5.5},{"Name":"Rumen","Price":6}]']);
        };
    </script>
</body>
</html>
```

Examples

Input	Output
`[{"Name":"Stamat", "Score":5.5}, {"Name":"Rumen", "Score":6}]`	<table> <tr><th>Name</th><th>Score</th></tr> <tr><td>Stamat</td><td>5.5</td></tr> <tr><td>Rumen</td><td>6</td></tr> </table>
`[{"Name":"Pesho", "Score":4, " Grade":8}, {"Name":"Gosho", "Score":5, " Grade":8}, {"Name":"Angel", "Score":5.50, " Grade":10}]`	<table> <tr><th>Name</th><th>Score</th><th>Grade</th></tr> <tr><td>Pesho</td><td>4</td><td>8</td></tr> <tr><td>Gosho</td><td>5</td><td>8</td></tr> <tr><td>Angel</td><td>5.5</td><td>10</td></tr> </table>
